- 1) This resistance value is much higher than any fuel injector resistance specification. This high level of resistance would cause less than normal current to flow and the injector would not likely be able to open.

- 2) The voltage drop across each injector should be within 0.1 volt of each other. If an injector has a higher-than-normal voltage drop, the injector windings have higher-than-normal resistance.

- 3) To test a fuel pressure regulator, the following steps will be necessary.  
Step #1 – Connect a fuel pressure gauge.  
Step #2 – Start the engine and observe the fuel pressure.  
Step #3 – Disconnect the vacuum line from the fuel pressure regulator and observe the pressure gauge. The pressure should increase about 10 psi.  
Step #4 – Using a hand-operated vacuum pump, test to see that the fuel pressure regulator can hold vacuum.  
Step #5 – Replace the rubber vacuum hose with a clean hose and start the engine. Check to see if there is fuel flowing through the clean hose, which would indicate a leak in the fuel pressure regulator.

- 4) The fuel injectors at the end of the fuel rail or located at bends in the fuel rail tend to become clogged because the fuel tends to slow down at these points and any dirt or varnish in the fuel tends to fall and partially clog the injector filter basket.

- 5) Fuel injectors can be tested for proper resistance, voltage drop, and pressure drop, as well as observed on a DSO for proper waveform, using both voltage and current.
